1 INTRODUCTION

Aquafor Beech Limited (Aquafor), in conjunction with Schollen & Company Inc. (Schollen) were retained by the City of Mississauga to undertake a Class Environmental Assessment (EA) and Detailed Design for Applewood Creek where watercourse erosion and degradation have created risks to public health and safety, as well as loss of golf course's property and infrastructure. Within the study area, Applewood Creek runs southerly through the Lakeview Golf Course as presented in Figure 1-1 below.

Figure 1-1. Applewood Creek Study Area – Lakeview Golf Course.

The EA for the study area was completed and filed on September 29th, 2020, through which Natural Channel Realignment of Applewood Creek within the study area was selected as the preferred alternative. The intent of this design brief is to summarize the detailed design of the preferred alternative, as well as the technical requirements associated with the detailed design drawings.

2 STUDY AREA EXISTING CONDITIONS

Applewood Creek, with a drainage area of approximately 411 hectares, is the easternmost watercourse within the jurisdiction of Credit Valley Conservation (CVC) and flows directly into Lake Ontario. The watercourse is located within an urbanized watershed that encompasses various land uses, including residential, commercial and open space.

Specific to the ~1300m corridor within the study area, Applewood Creek runs through the Lakeview Golf Course between the Dixie Outlet Mall and CN railway. The creek is channelized and was previously lined with engineered gabion banks along its entire length as a means to mitigate erosion and channel migration. Although efforts have been made by the golf course to constantly patch and repair the gabion baskets, these structures are approaching the end of their life-span. Throughout the golf course, the baskets have become outflanked and are devoid of stone at the base, causing the top courses to fall into the creek and posing significant risks to the safety of golf course users.

Moreover, in this case Applewood Creek is regarded as a natural hazard within the golf course, which if creatively integrated with the golf course layout, will improve aesthetics and enhance playability and the strategy of play, providing golfers with an enjoyable and memorable golf experience. However, in its existing condition, Applewood Creek does not add any beauty to the course and the current alignment of the watercourse is not very well incorporated to complement the playability of some of the golf holes. For example, the existing creek crossing Lakeview's 8th hole presents a 160-200-yard distance for a golfer's tee shot to carry the creek. This is a significant carry for beginner, intermediate and senior golfers.

A photo compilation of the existing conditions of Applewood Creek is provided in Figure 2-1, highlighting the confined nature of the watercourse and its position and context within the golf course setting.

March 8, 2021

E. Bridge #8 in good condition with irrigation main in saddle.

A. Downstream culverts under CN railway, with mixed headwall materials – historical brick and more recent gabion baskets.

B2. Slumping gabion baskets undermining and scouring around chamber structure

F. Deteriorated gabion baskets with top layer leaning towards the creek, posing safety risks to golf course users

B1. Bank scour and planform adjustment due to failure of gabion baskets.

C. Failure of gabion and unstable slope undermining mature vegetation in proximity to maintenance building & parking

D. Creek in proximity to 12th fairway and 16th green. Constraints of limited space to form natural meanders.

G. Applewood Creek at the upstream limit of the golf course, through a confined channel adjacent to Dixie Mall.

Figure 2-1. A Photographic Compilation of the Existing Conditions.

2.1 Geomorphic and Erosion Assessment

The Applewood Creek watershed is an urbanized watershed which lies within the lowland area of Lake Ontario. The watershed has relatively low gradients and is sensitive to water level fluctuations in Lake Ontario. Engineered erosion protection measures, in the form of gabion-lining along the banks, have been installed along the creek throughout the golf course. These gabions have been deteriorating and failing since the time of their installation and have required significant maintenance efforts from the golf course on an annual basis to minimize erosion impacts on the golf course.

An investigation of the historical alignments of the creek corridor provided insight into, and an understanding of the existing conditions, particularly related to mass changes to the alignment, and the natural tendencies of the creek to return to pre-disturbed conditions, while establishing parameters for unstable levels of shearing and flow velocities.

A compilation of the historical maps and aerial photos is presented in Figure 2-2 below, which highlights some of the following key features:

- 1859 – Applewood Creek in its historical alignment running down the centre of one single lot between Lakeshore Road and Middle Road. The property was owned at that time by Robert Campbell.
- 1877 – The lot was subdivided into three parcels. The historical alignment of Applewood Creek remained unchanged.
- 1909 & 1918 – The High Park Golf and Country Club was relocated to the area in 1907 and was renamed as the ‘Lakeview Golf and Country Club’ in 1912. The historical alignment of Applewood Creek remained unchanged throughout this period.
- 1954 – Applewood Creek was re-aligned into its present planform within the golf course. The bridges were installed. The Toronto Golf Club was constructed on the east side of Dixie Road. The residential neighborhood which presently surrounds the Lakeview Golf and Country Club was partially constructed.
- 1966 – The residential neighborhood continued to grow, occupying the remaining farm lands on the east side of Applewood Road. Dixie Mall was constructed north of the golf course, with the upstream section of the creek truncated and piped beneath the mall property.
- 1977 – The irrigation pond was constructed southwest of the 90-degree bends in the alignment of Applewood Creek. The ‘Fairway’ condominium building at 1400 Dixie Road was also constructed at around this time.
- 1992 – The Dixie Mall was further expanded to include the building and parking areas to the southwest of the existing mall, resulting in the removal of the remaining vacant/vegetated lands. Applewood Creek was lined with gabion baskets in the 1980s.
- 2015 – Erosion and undermining of gabion baskets necessitated significant maintenance efforts from the golf course. A number of trees on the northeastern slope between the pond and the maintained building fell. The last remaining piece of the open land in the area (Owls Head Road, Carnegie Drive, and Haig Blvd) was developed into a residential townhouse community.
- 2019 – Existing conditions included failing gabion baskets and undermined bridge abutments. The creek became unsightly and did not contribute to the aesthetic quality of the golf course.

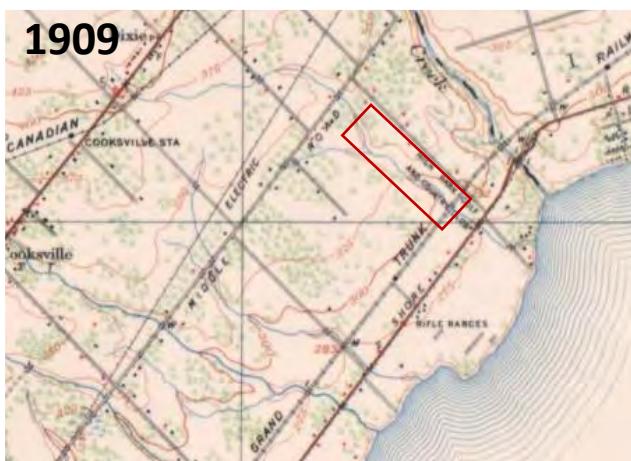

Figure 2-2. Historic Comparison of Maps and Aerial Imagery.

When completing a geomorphic assessment, it is common practice to refer a segment of watercourse that exhibits similar channel form, floodplain access, adjacent landuse and valley setting as a ‘Reach’. Based upon the historic aerial imagery and field reconnaissance, Applewood Creek within the study area is considered as a single reach of uniformly gabion-lined watercourse, which has a consistent depth and width throughout.

The geomorphic conditions of Applewood Creek within the study area are negligible, as the entirety of the channel is considered engineered. That said, there is evidence of intermittent baselevel lowering, which can further exacerbate the gabion basket failure through undermining the structures. The bed materials (substrate) are primarily composed of thin layer of gabion stone actively being sourced from areas where gabion baskets are failing at the base. There are intermittent outcroppings of shale bedrock amongst the gabion, however, degradation rates are controlled by the veneer of gabion.

With regards to planform development and consideration of horizontal erosion hazards, the Technical Guide River & Stream Systems: Erosion Hazard Limit (MNRF, 2002) can be applied to this study area. The erosion hazard limit is illustrated in cross section in Figure 2-3, followed by Table 2-1 which summarizes the typical erosion allowances associated with a natural channel setting. This information is presented as reference to inform the susceptibility to erosion of Applewood Creek over a long-term horizon. As identified above that the creek banks are entirely engineered along its length and exhibit signs of stress and erosion, the existing erosion hazards within the creek corridor are relatively low. Moreover, no slope stability concerns are present within the study area where no valley slopes exist. However, if the existing baskets continue to fall without intervention, extensive erosion and loss of tableland are expected to happen in a short timeframe. This elevated erosion rate can be as great as 15 meters in a 100-year time span, causing loss of tableland of the golf course and risks associated with safety.

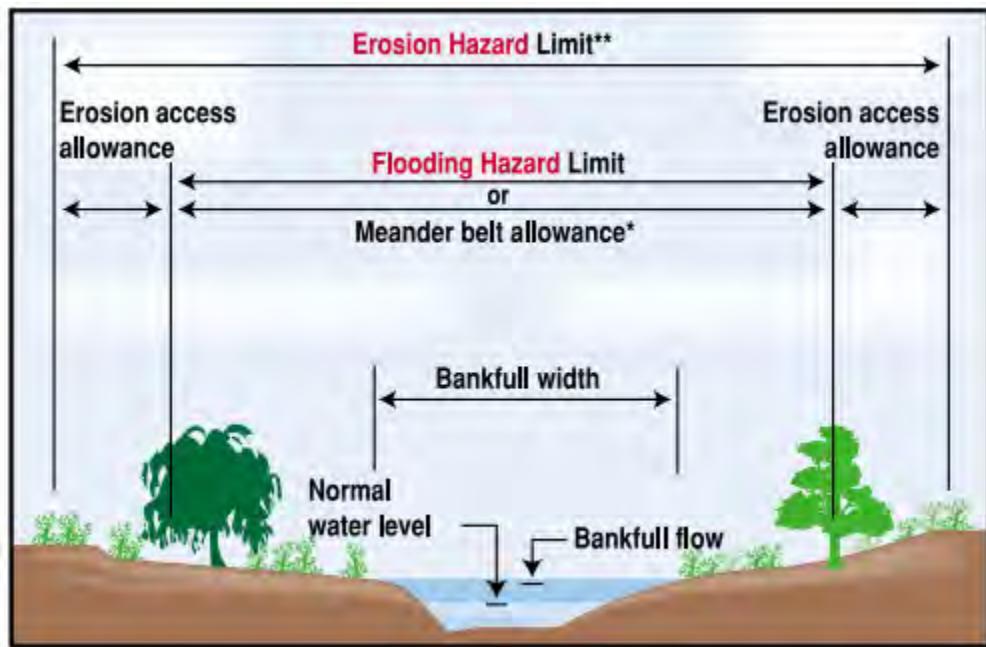

Figure 2-3. MNRF Guideline for Determining an Erosion Hazard Corridor within Unconfined Systems Such as Applewood Creek.

Table 2-1. MNRF Erosion Allowance Guidelines for Watercourses in Valley Settings.

MINIMUM TOE EROSION ALLOWANCE - River within 15 m of Slope Toe *				
Native Soil Structure	Type of Material Evidence of Active Erosion** or Bankfull Flow Velocity > Competent Flow Velocity***	No Evidence of Active Erosion** or Flow Velocity << Competent Flow Velocity***		
		Bankfull Width		
		< 5 m	5 - 30 m	> 30 m
1. Hard Rock (granite)	0 - 2 m	0 m	0 m	1 m
2. Soft Rock (shale, limestone) Cobbles, Boulders	2 - 5 m	0 m	1 m	2 m
3. Stiff/Hard Cohesive Soil (clays, clayey silt) Coarse Granular (gravels), Tills	5 - 8 m	1 m	2 m	4 m
4. Soft/Firm Cohesive Soil Fine Granular (sand, silt), Fill	8 - 15 m	1 - 2 m	5 m	7 m

* If a valley floor is > 15 m width, still may require study or inclusion of a toe erosion allowance.

** Active Erosion is defined as: bank material is bare and exposed directly to stream flow under normal or flood flow conditions and, where undercutting, over steepening, slumping of a bank or high down stream sediment loading is occurring. An area may be exposed to river flow but may not display "active erosion" (i.e. is not bare or undercut) either as a result of well rooted vegetation or as a result of shifting of the channel or because flows are relatively low velocity. The toe erosion allowances presented in the right half of Table 2 are suggested for sites with this condition.

*** Competent Flow velocity; the flow velocity that the bed material in the stream can support without resulting in erosion or scour. Consideration must also be given to potential future meandering of the watercourse channel.

2.2 Hydrologic & Hydraulic Assessment

A review of the study area hydrology and hydraulic conditions was undertaken to determine the existing flood levels / floodlines of Applewood Creek through the golf course, as well as to gain an understanding of the hydraulic parameters observed under the range of flood flow conditions which attribute to erosion and channel alteration.

2.2.1 Existing Hydrologic Conditions

At the onset of the study, a hydraulic (HEC-RAS) model was obtained from CVC which addresses a range of hydrologic conditions (i.e., flood flow scenarios), including the Regional event and return period events for 2-year, 5-year, 10-year, 25-year, 50-year, and 100-year storms. Table 2-2 below summarizes the range of flood flows of Applewood Creek through Lakeview Golf Course.

Table 2-2. Summary of Applewood Creek Flow Regime through Lakeview Golf Course.

Return Period	2-year	5-year	10-year	25-year	50-year	Regional	100-year
Flow (m ³ /s)	12.7	19.7	27.5	34.7	41.8	42.3	49.7

2.2.2 Existing Hydraulic Conditions

Existing Regulatory Model

A Regulatory HEC-RAS model of Applewood Creek representing its existing conditions was provided by CVC at the onset of the project. As per the model description, this existing Regulatory HEC-RAS model was most recently updated in May 2019. The existing model covers a length of approximately 2.8 km of the Applewood Creek from the Dixie Outlet Mall to the Lake Ontario, with the study area bounded by station 12591 and 11310. The cross-section arrangement of the study area within the entire model extent is presented in Figure 2-4.

Figure 2-4. Existing CVC HEC-RAS Schematic of Applewood Creek.

An existing Regulatory Flood Hazard Map (2020) through the study area was also provided by CVC and presented in Appendix A. Review of the CVC Regulatory flood hazard map and Table 2-2 suggests that the 100-year return flood defines the Regulatory floodplain limit within the study area. It is also noted that a significant portion of Lakeview Golf court is within the floodplain, with an identified spill area over the CN railway, which defines the downstream boundary of the study area. In turn, Aquafor recognizes the presence of sensitivity with regard to flooding of Applewood Creek within the study area.

Updated Existing Conditions Model

Opportunities to further improve the accuracy of the existing CVC model were taken to create the Updated Existing Conditions model, with the cross-section geometry updated for all stations within the study area, highlighting the continued channel erosion due to failure of the gabion baskets. These updates were based on a combination of the most recent topographic survey data undertaken by Aquafor and LiDAR data collected by Airborne Imaging in 2014-2015.

The Existing Regulatory model and Updated Existing Conditions model were run under a mixed flow regime, consistent with the setup of the base model. The resulting Regional water surface elevations of the updated existing condition model were compared to those under existing conditions, as summarized in Table 2-3. A complete table of hydraulic results is provided in Appendix B.

Table 2-3. Comparison of Water Surface Elevations (CVC Existing Vs. Updated Existing).

Minors changes in the resulting water surface elevations were observed when comparing the Updated Existing Conditions to the existing CVC model. These changes ($\leq 0.1\text{m}$) are explained by the updated channel bed elevations based upon the most recent topographic survey within the study area.

Additional hydraulic parameters were also reviewed from the Updated Existing Conditions model in order to provide insight into aspects such as erosive potential under a range of flood flow conditions. Summarized below is a suite of parameters associated with the range of flood flows from 2-year through to 100-year and Regional, for the creek and overbank lands in Table 2-4.

Table 2-4. Summary of Updated Existing Hydraulic Conditions for the Applewood Creek.

Flood Event	Flow (m ³ /s)	Channel Velocity (m/s)		Channel Shear (N/m ²)		Channel Power (N/m s)	
		Avg.	Max.	Avg.	Max.	Avg.	Max.
2yr	12.7	1.7	2.5	52.8	103.1	99.9	246.8
5yr	19.7	1.8	3.1	57.5	162.0	117.9	509.1
10yr	27.5	1.8	3.0	56.7	162.9	119.0	484.4
25yr	34.7	1.9	3.1	58.8	169.9	129.8	519.9
50yr	41.8	1.9	3.2	62.8	176.7	144.0	560.5
Regional	42.3	1.9	3.2	62.9	178.6	144.9	569.7
100yr	49.7	2.0	3.1	65.3	159.9	152.5	396.1

Review of the above tables highlights that Applewood Creek, experiences moderate to high shearing forces, channel power, and velocities under range of flood flow conditions. These high hydraulic forces carried by the Creek can contribute to increased levels of erosion and channel activity. These conditions have been considered when defining types of slope and bank stabilization opportunities, sizing and resistance thresholds of materials, and channel form.

2.3 Fish Habitat Assessment

A fish habitat assessment was completed on April 9, 2019 as part of the EA, using the Rapid Assessment Methodology for Channel Structure of the Ontario Stream Assessment protocol (OSAP) (Section 4: Module 1, Stanfield 2017). The site used for the OSAP assessment was located upstream of the northern side of the GO Train line culvert and extended approximately 1.4 km upstream to the southern limit of the Dixie Outlet Mall. This site was selected to provide a representative view of the study area. The fish habitat assessment field sheets are provided in Appendix C. A field inspection of the watercourse was conducted downstream of the study area to gain an understanding of the condition beyond the southern limit of the study area.

At the time of sampling, the average wetted width of Applewood Creek was 2.5 m. The average depth of the watercourse at crossovers was approximately 15 mm, with a maximum sampled depth of nearly 600 mm. The assessment suggests that the site consisted predominantly of shallow-to-medium-depth glides (hydraulic head of 4-7 mm), slow riffles (8-17 mm), and fast riffles (> 17 mm), as well as three deep pool habitats. Instream cover is low and consists of unembedded flat rock (at 33.3% of the observation points) and embedded flat rock (at 11.7% of the observation points). Substrate point particles are mainly gravel, with bedrock as the maximum particle.

Instream vegetation is comprised of filamentous algae. Overhanging vegetation is minimal but trees provide moderate canopy cover. Throughout the study area, riparian vegetation contributed to a canopy cover of 15%, since the vegetation community that is located along much of the length of the banks comprised maintained turf grass right up to the edge of the gabion-lined banks.

No major barrier to fish passage were observed within the study area. No fish were observed at the time of the assessment, however a dead *Lepomis* species was observed within the pool downstream of a footbridge.

2.3.1 Fish Communities

The Action Plan to Restore the Mississauga Shoreline (CVC, 2018) noted that Applewood Creek receives flow from Etobicoke Creek during high flow events; i.e., it has connectivity with a fish-bearing watercourse. That document further noted that warmwater fish species can access the creek upstream of Lakeshore Road as a result of culvert improvements (CVC, 2018). This was confirmed during site investigations that were conducted by qualified biologists who walked the corridor from the confluence at Lake Ontario to the downstream limit of the study area. No barriers were observed downstream of the GO Train crossing. While no specific fish community information was available for the study area, multiple sources, including an Angler Workshop conducted by CVC indicated that multiple (5) fish species had been found within the tributary (MacMull, 2015). This

information, combined with the noted connectivity to a fish-bearing watercourse (Etobicoke Creek) and Lake Ontario, along with the observation of an unknown *Lepomis* species within the study area, indicated that Applewood Creek (within the study area) should be considered to be fish habitat, since it meets the test of supporting fish at any time during any given year and/or connected to waterbodies that support fish at any time during any given year.

According to the Department of Fisheries and Oceans Canada (DFO) Aquatic Species at Risk (SAR) Map tool, no SAR are found (or potentially found) within the study area and no critical habitat for aquatic species at risk is present within the study area (DFO, 2019).

2.4 Terrestrial Resources Assessment

2.4.1 Vegetation Communities and Flora

Due to its location on an active golf course, the study area contains no natural vegetation communities except for a narrow, linear wooded feature that is located on the south side of Applewood Creek near the northwestern project limits. This community was described in the City of Mississauga's 2018 Natural Areas System Update (Site LV14) as a Willow Lowland Deciduous Forest (FOD7-3) community type. The 2018 Natural Areas System Updates and associated mapping for the study area (Site LV14) are included in Appendix D. Species observed by Aquafor Beech's field staff in this area include: Crack Willow (*Salix x rubens*), Manitoba Maple (*Acer negundo*), Sweet Cherry (*Prunus avium*), Green Ash (*Fraxinus pennsylvanica*), Siberian Elm (*Ulmus pumila*), Black Walnut (*Juglans nigra*), and Silver Maple (*Acer saccharinum*). Ash trees in this area were noted to be affected by invasive pest species Emerald Ash Borer (*Agrilus planipennis*). Invasive species such as Garlic Mustard (*Alliaria petiolata*), European Buckthorn (*Rhamnus cathartica*), and Dog-strangling Vine or European Swallow-wort (*Vincetoxicum rossicum*) were documented in this unit and it was noted to be highly disturbed by adjacent human activities/developments.

A single Butternut (*Juglans cinerea*) tree was observed directly adjacent to Applewood Creek in this vegetation community. Butternut is an Endangered species due to the widespread effects of the introduced Butternut Canker fungus (*Ophiognomonia clavigignenti-juglandacearum*). A Butternut Health Assessment (BHA) per provincial requirements was completed for this tree on July 4, 2019, at which time it was determined to be a Category 2 tree ("retainable"). DNA testing for hybridity was not completed but a visual inspection did not provide any evidence to suggest the tree was not a genetically-pure Butternut. The observed butternut was tagged as No. 259 and is depicted in Figure 2-5.

The rest of the site consists of scattered trees within a manicured turf grass landscape. City Forestry maintains a comprehensive set of tree inventory data within the Lakeview Golf Course. Aquafor Beech supplemented this inventory in 2019 as trees within the FOD7-3 forest unit described above had not been previously inventoried. The combined inventory data provides a complete overview of the trees that are growing along Applewood Creek within the study area such that any proposed tree removals may be quantified to determine compensation requirements in accordance with City of Mississauga and CVC standards. A total number of 1896 mature trees were included in the combined inventory, as included in Appendix D.

Figure 2-5. Observed Butternut Tree within Study Area.

2.4.2 Breeding Birds

The City of Mississauga's Natural Areas System Update (2018) lists a number of bird species in association with Site LV14 which overlaps the study area. Most of these bird species are common in suburban parkland and residential neighborhoods. However, one species is a designated SAR: Chimney Swift, which is listed as Threatened both provincially and federally. This species nests almost exclusively in human-made structures (i.e., chimneys) and therefore does not have any nesting habitat present in the study area. It could, however, be nesting in nearby buildings and foraging over the golf course property.

The active nests of most migratory birds are protected under the federal *Migratory Birds Convention Act* and/or the provincial *Fish and Wildlife Conservation Act*. Actions that may cause harm to bird nests (e.g., removal of vegetation) should preferentially be planned to occur outside of the typical bird nesting season which extends from April 1 to August 31 in any given year.

2.5 Ministry of Natural Resources and Forestry (MECP) Species at Risk Screening

For the purpose of this study, SAR are defined as those species designated as Endangered (END), Threatened (THR), or Special Concern (SC) under the provincial *Endangered Species Act* and/or the federal *Species at Risk Act*. Aquafor Beech completed a screening exercise for SAR within the study area using background data (e.g., the NHIC's database, the City's Natural Areas System Update, citizen science databases such as eBird and iNaturalist, etc.) and correspondence with the Ontario Ministry of the Environment, Conservation, and Parks (MECP) to identify species with the potential to occur in the vicinity. These species were then assessed by comparing their habitat requirements with the habitat present in the study area.

2.5.1 Butternut – Present – Endangered

As previously documented, Butternut (END) was found in the study area directly adjacent to Applewood Creek in lowland forest habitat. It was observed growing right at the edge of the gabion basket and therefore will be impacted by the proposed removal of the baskets. The proposed design is intended to retain this butternut tree, noting that wire meshes of the gabion baskets are to be removed with caution to limit damages to the roots. IGF submission process will allow MECP to review the proposed works and determine the requirements for registration, permitting, or other actions regarding the Butternut on the property.

2.5.2 Chimney Swift – Potentially Present / Non-Breeding – Threatened

Chimney Swift historically nested in deciduous and coniferous, usually wet forest types, all with a well-developed, dense shrub layer. Nesting sites today are mostly found in urban areas in large and uncapped chimneys. Chimney Swift was documented by background sources as being present in the vicinity of the study area; however, this species is not considered to have any suitable nesting habitat in the study area.

2.5.3 Barn Swallow – Potentially Present / Non-Breeding – Threatened

Barn Swallow (*Hirundo rustica*), a Threatened bird species, was noted in the vicinity of the study area by several background sources. This species, like Chimney Swift, typically nests on human-made structures; it is known to use the underside of bridges for nest construction (COSEWIC, 2011). However, Barn Swallow is not considered to be a factor in this project due to the absence of suitable nesting habitat (i.e., vertical riverbanks or other eroded faces; COSEWIC, 2013) in the study area. While Aquafor Beech's field staff did not note any Barn Swallow nests on the underside of golf course bridges along Applewood Creek, it is recommended that the site be reviewed again prior to construction to confirm the absence of nests as nesting sites are not necessarily static from year to year.

2.6 Archaeological Assessments

Stage 1 archaeological assessment was carried out by Archaeological Services Inc. (ASI) in May 2019. The assessment included review of background documentation and property inspection to determine if the study area exhibits any archaeological potential. As a result, the Stage 1 assessment indicated that part of the study area (orange & green areas highlighted in Figure 2-6) exhibits archaeological potential and requires a Stage 2 assessment.

Stage 2 archaeological assessment involving further site investigations and test pit surveys were then undertaken by ASI on May 19-21, 2020. In addition, First Nation groups, including the Haudenosaunee Development Institute (HDI), Huron-Wendat First Nation (HWFN), and the Mississaugas of the New Credit First Nation (MCFN) were invited to attend the Stage 2 on-site assessment. HDI and HWFN were able to provide on-site liaisons, and daily fieldwork submissions were provided to MCFN through the Archaeological Consultant Daily Submission Form. No archaeological resources or intact A-horizon were encountered during the Stage 2 test pit survey. The Stage 2 archaeological assessment report is included in Appendix E.

Figure 2-6. Results of the Stage 1 Archaeological Assessment. (ASI, 2019)

2.7 Heritage Impact Assessments

Lakeview Golf Course is designated by the City of Mississauga as a ‘Heritage Landscape’ under Part IV of the Ontario Heritage Act. As such, it is essential that the proposed erosion control and watercourse restoration works do not pose a negative impact on the features of the golf course that have heritage values based on the designation and that the proposed works are fully integrated with the golf course landscape.

A Heritage Impact Assessment (HIA) for the golf course was completed by ASI as part of the EA, which identified all existing cultural heritage features and confirmed that the proposed channel and golf course rehabilitation works will not create negative impacts on the cultural heritage value of the golf course. The configuration of Applewood Creek is an original feature and a heritage attribute of the course.

Since Lakeview Golf Course is designated under the Ontario Heritage Act, a Heritage Permit will be required to facilitate any alterations of the property. Upon finalization, this detailed design will also be submitted to the City’s Heritage Advisory Committee for review and comment.

2.8 Land Ownership and Easements

The study area is located within the Lakeview Golf Course which is a city-owned property. The Region of Peel owns an easement over top of the sanitary sewer infrastructure that traverses the southeast corner of the golf course. The sanitary sewer crosses the creek ~60m upstream of the CN railway. Detailed designs of the proposed channel within the sanitary sewer easement will be submitted to the Region for review and approval, with the intent to maintain the existing cover depth above the sanitary sewer crossing.

3 DESIGN FACTORS

During the process of developing the detailed design for Applewood Creek erosion controls, it is imperative that all conditions and constraints for the channel are identified at the onset of the design. This ensures that they are adequately considered while developing various elements of the design. While several of the constraints and conditions are common to any design project, several are unique to this study area. Constraints and considerations identified within the study area were as follows:

Design Flow – Hydraulic conditions anticipated in the channel for the full range of flow events should be considered when determining suitable substrate sizes. Hydraulic modelling of the Applewood Creek study extent was performed using the U.S. Army Corps of Engineering HEC-RAS model. The model has been provided by CVC and modified by Aquafor for the purposes of this study. The flow profiles in CVC’s baseline model are used for all modelling scenarios.

Upstream and Downstream Tie-in Points - Care must be taken to ensure that there is a smooth transition into, and out of, the modified channel sections such that a continuity of channel form and process occurs, and that the stability of the constructed works is not compromised. This is accomplished by ensuring that the proposed channel modification is properly tied-into the existing creek at the Dixie Outlet Mall and the existing culverts under CN railway at the downstream end.

Low-Traffic Bridge Crossings – To accommodate the proposed channel and golf course restoration works, all none (9) existing pedestrian/cart bridge crossings will be removed. Five (5) new bridges are proposed to facility pedestrian and golf cart traffic. The proposed bridges are considered as and will be designed to meeting the standards for “Low Traffic Pedestrian Crossings” as defined in the CVC’s Technical Guidelines for Watercourse Crossings.

Creek Corridor with Golf Course Setting - Applewood Creek is regarded as a natural hazard within the golf course. In turn, the proposed channel restoration should be creatively integrated with the golf course layout, such that it improves aesthetics, playability and the strategy of play, as well as providing golfers with an enjoyable and memorable golf experience.

Storm Sewer Outfalls – Two (2) storm sewer outfalls are located within the proposed work areas, which have deteriorated. These storm outfalls will be restored and retrofitted into the proposed channel alignment.

Sanitary Sewer Crossings – Region of Peel’s sanitary trunk sewer crosses the channel near the downstream limit of the study area. In the proposed design, the existing cover of the sewer crossing will be maintained, in order to protect the sewer lines.

Disturbance to Terrestrial Vegetation – Mature trees and other vegetation are designated cultural heritage attributes of the Lakeview Golf Course, protected under the Ontario Heritage Act. The proposed design will endeavor to limit the number of trees required for removal. However, whenever trees are required for removal to facilitate construction, new trees consistent with City of Mississauga and Credit Valley Conservation requirements be replanted. As a number of potentially suitable maternity roosting trees for endangered bats are located within the study area, considerations will be given to minimize disturbance to those trees as well.

Low Flow – To ensure sufficient water depth for potential fish passage at structures, a low flow channel is required to concentrate flows in the riffle design.

Enhancement of Aquatic and Terrestrial Habitat – Efforts will be made to enhance terrestrial and aquatic habitats of Applewood Creek within the study area due to the creation of low flow channel and riparian plantings.

The sections below detail the various components of the design, subject to the above-mentioned considerations and constraints

3.1 Channel Form and Profile

Throughout the study area, the proposed channel restoration is contained within the City-owned golf course. Re-meandering of the channel is incorporated in the detailed design, with consideration of the watercourse blending into the golf course setting and being part of the play. The channel is significantly realigned within the middle section, where the design removes the existing irrigation pond and the proposed channel shifted away from the slope below the maintenance building. Locations of the riffles and pools were selected to minimize excavation, placing riffles on straight sections and pools on bends, and providing riffles at bridge crossings where possible. An average channel width of 10.3m is maintained, allowing a bankfull discharge approximately equivalent to the 2-year flood. Vegetated banks, with lifts of boulders, soil mix and vegetation plantings, are proposed long outer bends and runs to further stabilize channel banks and prevent bank failure from long-term erosion.

The proposed longitudinal profile provides a riffle-pool sequence, following the planform configuration. With fixed tie-in elevations at both ends, the proposed channel maintains the same average slope as the existing channel, with grades on the proposed riffles ranging from 1.5% to 2.5%. The proposed pool depth is maintained at 0.3m throughout the design, which provide potentials for fish habitat development.

Cross sections of typical riffles and pools are depicted in Figure 3-1 below. Profile details for arrangement of each riffle and pool feature are demonstrated on the detailed design drawings.

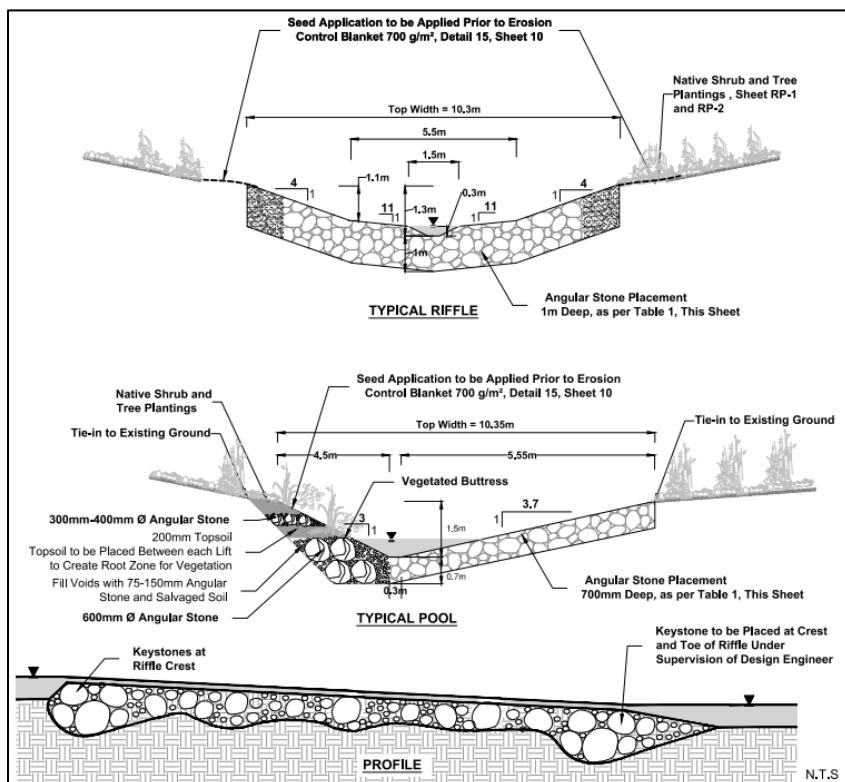

Figure 3-1. Typical Detail of Proposed Riffles and Pools.

As shown in the cross-section drawings, channel bed is to be constructed with a layer of angular stone mixture and the outer banks of the pools with vegetated boulders. The larger boulders placed at the toe of bank slopes are sized with a diameter of 0.6 (24 inch) which have a permissive shear stress and velocities of 483.6 N/m² and 5.49 m/s respectively (Table 3-4), surpassing the maximum shear and velocities that the channel experiences under all flow scenarios given in Table 3-3. The following sections will further explain the sizing of riffle materials.

3.2 Hydraulic Assessment

A Proposed Conditions scenario was developed to estimate hydraulic impacts of the proposed restoration work. The geometry of the Updated Existing conditions model was updated to generate the Proposed Conditions model as per the design. The geometry of cross sections, and the channel centerline from station 12591 to station 11310, were modified to reflect the proposed design including five (5) new bridges. The arrangement of the Proposed Conditions model cross-sections is depicted in Figure 3-2.

Figure 3-2. Arrangement of Cross Sections in the Proposed Conditions HEC-RAS Model.

3.2.1 Water Surface Elevations

The Proposed Condition model was used to estimate impacts of the proposed design on the water surface elevations for the return period flows and the Regional event. A summary of the resulting water surface elevations from the Proposed Conditions for the 100-year and 2-year events is presented in Table 3-1 and Table 3-2 respectively, in comparison to the Updated Existing Conditions water surface elevations. A complete table of hydraulic results for all three model scenarios is presented in Appendix A.

Table 3-1. Comparison of HEC-RAS 100-year Water Surface Elevations (Updated Existing Vs. Proposed).

12.7	11310	86.48	11310	86.51	0.03
13.3	11294	86.54	11294	86.54	0
11276 Culvert / 4-CNR					
13.3	11258	85.69	11258	85.69	0

Review of tables above suggests that the proposed conditions water surface elevations and flooding conditions are significantly reduced within most areas of the study area under both flow regimes. Under the Regulatory (100-year) event, an increase in flooding was only observed at station 11928, downstream bounding cross section of an existing bridge. This increase of 0.07m can be explained due to the removal of the bridge and regrading of the area in the proposed design. For the 2-year event, only a minor increase of 0.03m was observed at the downstream boundary of the study area at station 11310. This 0.03m increase in water surface elevation is within the model accuracy and contained within golf course. Moreover, it is noted that these increases of water surface elevations have minimal impact on the Regulatory floodplain and will not impact the flooding conditions at the CN railway. An updated mapping of 100-year floodplain for the Updated Existing and Proposed Conditions models is depicted in Figure 25 below

Figure 3-3. Comparison of Updated Existing and Proposed 100-year Flood Limits (49.7m³/s).

3.2.2 Hydraulic Parameters

Key hydraulic parameters from the Proposed Conditions HEC-RAS model output are summarized in Table 3-3 below, indicating the velocity and forces that the proposed channel experiences during a range of flood events.

Table 3-3. Summary of Proposed Hydraulic Conditions of Applewood Creek.

Flood Event	Flow (m ³ /s)	Channel Velocity (m/s)		Channel Shear (N/m ²)		Channel Power (N/m s)	
		Avg.	Max.	Avg.	Max.	Avg.	Max.
2-year	12.7	1.72	2.82	46.75	142.86	92.14	403.10
5-year	19.7	1.85	3.10	50.78	135.13	108.78	419.27
10-year	27.5	1.92	3.45	53.87	162.89	127.05	545.86
25-year	34.7	1.95	3.67	54.67	169.94	134.50	619.06
50-year	41.8	2.06	3.73	58.55	177.50	150.67	617.52
Regional	42.3	2.05	3.73	57.97	180.33	148.56	614.98
100-year	49.7	2.13	3.73	59.91	243.77	157.65	856.70

Review of the above tables, in comparison to Table 2-4, shows that the proposed channel is expected to experience similar hydraulic conditions to its existing condition. In turn, the design has considered the risks associated with bed incision and bank failure over long-term erosion as well as under extreme conditions when defining types of restoration measures and determining resistance thresholds for proposed channel substrates. Published data on critical erosional thresholds for various types of materials are presented in Table 3-4.

Table 3-4. Erosion Thresholds for Stream Bed and Bank Materials (Fischenich, 2001).

Boundary Material	Permissible Shear Stress	Permissible Velocity
	(N/m ²)	(m/s)
Fine Gravels	3.6	0.76
Stiff Clay	12.4	0.91-1.37
Alluvial Silt	12.4	1.14
Shales and Hardpan	32.1	1.83
Non-Uniform Gravel / Cobble		
2-inch	32.1	0.91-1.83
6-inch	95.8	1.22-2.29
12-inch	191.5	1.68-3.66
Rip-Rap		
9-inch D50	181.9	2.13-3.35
12-inch D50	244.2	3.05-3.96
18-inch D50	363.9	3.66-4.88
24-inch D50	483.6	4.275.49

Vegetated coir mat	191.5-383.0	2.9
Live brush mattress (initial)	19.2-196.3	1.22
Live brush mattress (grown)	186.7-392.6	3.66
Brush layering (initial/grown)	19.2-299.2	3.66
Concrete / Armourstone	598.5	5.49

3.2.3 Flow Conveyance Analysis

As aforementioned, the primary function of the proposed bridges is to allow golf carts and golfers to cross the creek during the play. In turn, these bridges are considered as “Low Traffic Pedestrian Crossings” and have in turn been designed to meet the minimum dimensions as required in the Guideline. Design criteria for “Low Traffic Pedestrian Crossings” and the proposed bridge dimensions are summarized in Table 3-5 and Table 3-6 respectively.

Table 3-5. CVC Low Traffic Pedestrian Crossing Design Criteria.

Criteria	Minimum Height = x (times) bankfull depth	Minimum Span = x (times) bankfull width
	$1\frac{1}{2} + 30\text{cm}$ when depth is greater than 60cm	$1\frac{1}{2}$ (or 1 for existing man-made channelization)

Table 3-6. Proposed Bridge Dimensions.

River Station	Bridge #	Soffit Elevation (m)	Channel Invert Elevation (m)	Height (m)	Span (m)	Width (m)
12270	Bridge 1	94.13	91.88	2.25	15.45	3
11995	Bridge 2	92.25	90	2.25	15.45	3
11872	Bridge 3	91.93	89.68	2.25	15.45	3.6
11549	Bridge 4	88.93	86.68	2.25	15.45	3
11405	Bridge 5	87.92	85.37	2.55	15.45	3

Flow conveyance analysis for all five (5) proposed bridges was performed in order to identify their conveyance capacities and overtopping conditions and examine these conditions against CVC's Technical Guidelines for Watercourse Crossings. Assessment results are provided in Table 3-7.

Table 3-7. Conveyance Flow Analysis for Proposed Bridges.

River Station	Bridge #	Max. Conveyance with Free Board	Max. Pressurized Flow without Overtopping	Min. Flow with Overtopping
12270	Bridge 1	100-year		
11995	Bridge 2	Regional	100-year	
11872	Bridge 3	100-year		
11549	Bridge 4	10-year	100-year	
11405	Bridge 5	5-year		10-year

Review of the results suggests that all proposed bridges, except for Bridge #5, will not be overtopped under storm events ranging from 2-year to Regulatory. Upon review of the flood profiles of the entire reach, it is noted that conveyance through Bridge #5 is largely restricted due to the backwater effect of the downstream CN culvert crossing.

3.3 Geotechnical Investigations

A detailed geotechnical investigation was undertaken by Terraprobe Inc. in April 2020, in order to define and characterize the subsurface soil and groundwater conditions within the study area, as well as providing geotechnical engineering recommendations for the design of the proposed pedestrian bridge foundations.

The field investigation consists of drilling and sampling a total of nine (9) boreholes to auger refusal depths of 2.1m to 3.9m below existing ground surface, in the vicinity of each of the proposed bridge locations. In summary, a surficial layer of topsoil was encountered at the ground surface in all boreholes. The topsoil was underlain by a layer of earth fill materials in some boreholes. The native deposits consisted of generally loose sandy silt to silty sand or sand which was in turn underlain by clayey silt glacial till deposit which extended to the inferred bedrock. The bedrock of the Georgian Bay Formation, typically found in the general area, is a deposit predominantly comprising thin to medium bedded blue-grey shale of Upper Ordovician age. The bedrock contains interbeds of grey calcareous shale, limestone and calcareous sandstone which are discontinuous and nominally 50-300mm thick.

Upon review of the subsurface soil and groundwater conditions identified within the study area, it is recommended that a conventional spread footing foundation approach would be the most feasible based on the relatively shallow depth of inferred bedrock.

The complete geotechnical report is included in Appendix F.

3.4 Substrate Sizing

The predicted shear stress and velocity values in the hydraulic model were reviewed to determine appropriate stone sizing for the channel substrate mix under proposed conditions. Channel shear stress values from the proposed model were used to determine the entrainable grain size using the critical shear stress equation derived from the Shield's equation (Robert, 2003):

$$\tau_{cr} = 0.728D \quad [1]$$

where τ_{cr} is the critical shear stress [N/m²]
 D is the grain size entrained [mm]

Transportable grain sizes were also considered in the analysis and were determined using the predicted velocities in the equation derived by Komar (1987):

$$v = 57D^{0.46} \quad [2]$$

where v is the velocity [cm/s]
 D is the grain size transported [cm]

Results from the hydraulic model and hydraulic analysis are included in Appendix A. The calculated mean values for grain sizes entrained and transported for the HEC-RAS sections throughout the study area are presented in Table 3-8. These values were used to inform the proposed channel substrate gradation.

Table 3-8. Mean Grain Sizes from the Hydraulic Analysis.

Flood Event	Mean Grain Size Entrained (Shield Equation)		Mean Grain Size Transported (Komar Equation)	
	Average (mm)	Max (mm)	Average (mm)	Max (mm)
2-Year (12.7 m ³ /s)	61	156	114	330
5-Year (19.7 m ³ /s)	67	186	137	431
Regional (42.3 m ³ /s)	73	335	165	650
100-Year (49.7 m ³ /s)	79	248	186	650

Review of the table above suggests that the mean grain size predicted by the model to be entrained is about 50 to 350mm for the 2-year through 100-year flood events. The estimated transportable grain size is about 100 to 650mm for the same range of flows. Applying a factor of safety, these values were used to determine the D₅₀ and D₈₄ of the substrate, which were then used to inform the substrate gradation as included in Table 3-9. The smaller material has been specified to fill the voids between the larger material and to contribute to fish habitat. Larger particles, keystones, are included to provide stabilization of the overall riffle structures, particularly at the riffle toe and crest under all potential flood flow conditions, including the Regional and range of return period events.

Table 3-9. Proposed Substrate Gradation.

Substrate Sizing		Percent Composition (%)	Accumulative Percentage (%)
(mm)	(in)		
50 – 150	2 - 6	15	15
150 - 300	6 - 12	20	35
300 – 450 (D ₅₀)	12 - 18	20	55
450 – 550	18- 21.5	15	70
550-750	21.5 - 29.5	15	85
750-900 (D ₈₄)	29.5 - 35.5	15	100

3.5 Bank Treatments

Vegetated buttresses are proposed to form banks of the outer bends to further stabilized the proposed channel while creating a more natural form. The vegetated buttresses are composed of layers of roundstone with the void space filled with smaller roundstone and native soil. The surface will be amended with topsoil, planted with native shrubs (potted stock), and terraseeded with a native seed mix. A detail is shown on Sheet CD-1 of the design drawing package. Upper banks of the runs and riffles of the proposed channel will consist of a 50/50 mixture of channel substrate and native fills. The hard materials are proposed to stabilize the banks with the native materials filling the voids and supporting vegetation growth.

3.6 Sanitary Sewer Crossings

Region of Peel’s sanitary trunk sewer, 2.4m diameter, crosses the proposed channel near the downstream limit of the study area, at chainage 1+220m. Protection of the sanitary sewer crossing is critical to this project as this sewer is integral to Peel’s collection system serving as the Region’s main eastern trunk sewer collection spine and cannot be isolated. The existing cover depth above the sewer crossing is ~2.8m which will be maintained by the proposed design. Risks associated with impact loads and heavy equipment live loads to the sewer will be assessed and confirmed with the Region that the proposed channel and construction activities do not undermine the integrity of this sanitary crossing. Mitigation measures to further protect the sewer during construction will also be considered, including placement of wood/steel mats on the riding surface over/near the sewer and pre-and post-construction CCTV inspection of the sewer.

A cross section of the proposed channel restoration through the sewer crossing is shown on Sheet XS-6 of the design drawing package.

3.7 Fish Passage

The design was also assessed to ensure fish habitat and passage potential are not negatively impacted throughout the study area. A fish passage assessment was performed for the proposed channel adjustment by evaluating channel velocities under frequent flow conditions. The low flow condition was estimated using the Ontario Flow Assessment Tool (OFAT). The User Guide suggests that the 1 in 10 years 3-day delay discharge (3Q10) be used when assessing fish passage. A 3Q10 discharge of 0.11 m³/s was estimated using OFAT, applying the Graphical Index Method (MOEE 1995). This flow condition was applied to the updated existing conditions and proposed conditions HEC-RAS model scenario, with simulation results for channel velocities summarized in Table 3-10.

Table 3-10. Channel Velocities Under Low Flow Conditions.

Model Scenario	Flow (m ³ /s)	Channel Velocity (m/s)		
		Median	Average	Maximum
Updated Existing	0.11	0.46	0.52	1.21
Proposed	0.11	0.58	0.58	1.05

The resulting channel velocities were then compared with fish swimming velocities from the Environmental Guide for Fish and Fish Habitat (MTO, 2006) summarized in Table 3-11.

Table 3-11. Fish Swimming Speeds (MTO, 2006).

Species End Life Stage (size, mm)	Sustained* Speed (m/s)	Prolonged* Speed (m/s)	Burst* Speed (m/s)
Small forage fish** (50 – 65 mm)	0 – 0.22	0.22 – 0.29	0.29 – 0.40
Medium forage fish** (90 – 110 mm)	0 – 0.31	0.31 – 0.68	0.68 – 0.76
Large forage fish** (180 – 230 mm)	0 – 0.42	0.42 – 0.95	0.95 – 1.11
Carp (adults)	0 – 0.4	0.4 – 1.2	1.2 – 2.6
Suckers (adults)	0 – 0.4	0.4 – 1.5	1.6 – 3.1
Brown Trout (adults)	0.0 – 0.7	0.7 – 1.9	1.9 – 3.9
Rainbow Trout (adults)	0.0 – 0.9	0.9 – 1.8	1.8 – 4.3

* Sustained speed can be maintained indefinitely.

Prolonged speed can be maintained for up to 200 minutes.

Burst speed can be maintained for up to 15 seconds. (Chillbeck 1992)

** Calculations based on a generalized relationship between fish length and swimming speed for species using the same swimming form (Katopodis and Gervais, 1991).

Comparison of velocities at low flow conditions suggest that the study area of Applewood Creek is currently passable to large forage fish and larger species, although channel velocities can exceed the burst speed of large forage fish within some localized sections. Maximum channel velocities under low flow conditions have decreased under the proposed condition, with minimal increase on the average velocity, so impacts to fish passage should not be negative overall. In addition, the estimated velocities of the proposed channel are well within the range of swimming speeds of White Suckers which were previously observed upstream of Lakeshore as documented in the Environmental Impact Study for 1345 Lakeshore Road East Land Development (ABL, 2018).

It is important to note that the existing aquatic habitat within Applewood Creek represents a disturbed watercourse in an urban area and supports a low diversity of fish community due to the degraded gabion lined banks and little in-stream vegetation cover. However, the intent of this project is to improve the existing condition in which better opportunities for fish habitat and passage may occur. In this regard, all gabion line banks are proposed to be removed and replaced with vegetated boulders and stones, along with proposed riffle profile sloping from 1.5-2.5%, considered well within the range of fish passage potential.

3.8 Enhancement to Golf Course Features

Given the architectural pedigree and cultural heritage value of Lakeview Golf Course, it is critical that any alterations to the golf features are designed in a restorative fashion, so that the restoration does not undermine the principles and style of the original design while accommodating the erosion protection objectives.

To accommodate the proposed natural realignment as per the preferred alternative, some changes to the golf course features are required, including some tees, fairways, greens, trees, and cart path. Therefore, Aquafor has worked collaboratively with Schollen's golf course architect throughout the project, with the intention to bring back the original layout (~1920s by Mr. Strong) where possible and to allow the proposed Applewood Creek corridor to become a more aesthetically and strategically prominent part of the golf course. The proposed restorative changes to each hole are summarized below.

Hole 1:

The 1st tee is proposed to be relocated and restored as an elevated tee shot as the proposed creek alignment traverse through the existing tees. Research suggested that the hole played at 350-yards during the 1923 Canadian Open, which is approximately 15-yards longer than its current length (Toronto Star 1923). As such, elevating the tee and lengthening the hole will be consistent with its original design.

Hole 5:

The restoration of Hole 5, a par 5, will be focused on enhancing the prominence of Applewood Creek and strengthening sightlines to the north side of the second landing area. This will require the removal of two spruce trees that are located to the left (northwest) of the green and the reconstruction of the cart path along the right (south) side of the hole.

Hole 8:

The alterations to Hole 8 will include the provision of connection from the forward tee-off to the fairway area by constructing a bridge over the watercourse. A new forward tee will also be re-constructed. The fairway is proposed to be re-contoured with additional landing width to improve playability of this hole, which can be achieved by changing the grass-cutting strategies.

Hole 16:

The restoration of Hole 16 will recapture the opportunity to use the natural topography on the left (north) side to direct the ball into the ideal landing area with a clearer sightline. This will require the removal of one spruce tree in the left rough, expansion of the fairway, realignment of the back tee, and relocation of the front tee. A review of historical aerial photographs suggests that there was no tree historically located on the left-hand side of the fairway prior to the 1980's, therefore, removal of the spruce tree will assist in restoring this hole to its pre-1980s state.

Moreover, the green is proposed to be enlarged to its anticipated original size, which is considered important in maintaining adequate turf health to the course (which hosts over 32,000 rounds of play each season). The green expansion will involve probing beyond the existing perimeter of the green and searching for remnants of the original green profile. If the green can be restored to its original size via this approach, it would be seen as a positive impact on the cultural heritage value of the course. Otherwise, if no remnants of the former green can be found, the expansion will be achieved by carefully matching surface grades and strategic grass-cutting to achieve a seamless transition. It is also important to note that the internal slope percentages within the green shall be maintained.

Hole 17:

The novelty of Hole 17 is its two sets of tees and greens (upper and lower). Based upon research of historical photographs and literature, the upper set appears to be original as designed by Mr. Strong in 1921, whereas the lower set was created in 1950-1960s and has since been altered several times, with the pond being constructed in 1977. The proposed alterations to Hole 17 include the restoration of the upper green size, to achieve the character and bunker configuration to that of 1921 green, as well as the removal of the lower green. A historic photo of the original 17th green is included in the Figure below, which is a strong example of the artistry and character of Mr. Strong who boldly located greens near ridgelines.

Figure 3-4. Lakeview Golf Course 17th Hole – 1921, Existing & Proposed Conditions.

3.9 Vegetation Restoration

In order for the proposed restoration to be implemented, some disturbance to the surrounding vegetation will occur. In an effort to minimize the disturbance, sediment and erosion control fencing will be erected at the onset of the construction and will be used delineate the extents of machinery access and minimize creep into surround areas. As indicated in Section 2.4, a detailed vegetation inventory was completed to enable tailoring the access and impacted areas to minimize mature tree removals.

A total of 175 trees were identified for removal to facilitate the proposed channel works, mostly consisting of non-native species (i.e., Manitoba Maples, Norway Maples, etc.) which are also mostly in poor health conditions and low preservation priorities. Following completion of construction, all disturbed areas will be restored as per the planting plan and details of the design drawings. All trees removed will be compensated at a 3:1 ratio. Native seed mixes will also be specified for the disturbed area. The seed mixes will be applied by Terraseeding with a cover crop to provide erosion protection as the permanent vegetation establishes.

Overall, the restoration plan provides an ecological benefit to aquatic and terrestrial habitats. Once established, shrubs and trees along the bank will provide over-hanging vegetation which will shade the creek and help maintain cooler water temperatures. Over-hanging vegetation also provides secondary inputs, such as insects and leaf litter, which contribute to aquatic habitat. Rooting masses of established plants will help to stabilize the bank and reduce sediment release. The use of native vegetation provides habitat for wildlife (e.g., food sources for birds) and will increase the vegetation diversity in the creek corridor. Detailed restoration plan including restored areas, species of trees and shrubs to be planted, and seed mix is shown on design drawings.

4 PERMITS AND APPROVALS

Prior to construction it will be necessary to coordinate environmental approvals and permits required to complete the intended works. At this time, it is Aquafor's understanding that approvals from CVC, MECP, DFO, Region of Peel, and City of Mississauga may be required. A brief summary of permits and approvals is included below:

CVC – O. Reg. 166/06 Permit – This typically involves two submissions (60% & 95% design) and will include supporting design brief information.

DFO – Assessment under the Federal Fisheries Act – Aquafor's certified fisheries biologist completed a Self-Assessment based on the detailed design for the proposed works. It was determined that application for a DFO Request for Review was necessary for the proposed Duncan Creek restoration design. A Request for Review will be submitted to DFO. Based on similar experiences, at minimum a Letter of Advice may be required from DFO.

MECP 17(2) (b / c) Species at Risk Permit – An Information Gathering Form (IGF) will be submitted to the MEC. Depending on the results of the IGF and further field investigations, MECP will confirm whether a SAR permit will be required.

Regional of Peel – Sanitary Sewer Easement – The proposed channel works within the existing Region sanitary sewer easement need to be approved by the Region.

City of Mississauga – Heritage By-Law - A heritage permit application will be submitted to the City's Heritage Advisory Committee, including the detailed design and Heritage Impact Assessment report.

SHEET INDEX

General Notes:

1. Contourlines on this map were generated by Airborne Imaging using the Spring of 2015 LiDAR point cloud, breaklines and hydrologic enforcement of bridges. The vertical accuracy of the original points is 0.10 metres RMSE.
 2. The planimetric data was obtained from the City of Mississauga in 2017.
 3. The vertical datum is mean sea level established by the CGVD 28, 1978 Southern Ontario adjustment.
 4. The horizontal datum is North American Datum 1983 CSRS (Epoch 2010) UTM Zone 17.
 5. The City of Mississauga has no responsibility for the data.

Appendix D – Detailed Tree Inventory

Tag #	Species Name		Tree Dimensions		Health Condition	Notes	Action
	Scientific Name	Common Name	DBH (cm)	Crown Reserve (m)			
217	<i>Tilia americana</i>	Basswood	62, 35	12.0	P-F	Cavity at base of tree. Dead and broken branches.	Retain
218	<i>Acer negundo</i>	Manitoba Maple	64	10.0	F	Broken leader and cracks.	Retain
219	<i>Acer negundo</i>	Manitoba Maple	14, 7	5.0	P-F	Broken branches, suckers. Previously pruned.	Retain
220	<i>Acer negundo</i>	Manitoba Maple	17, 16	5.0	F	Codominant leaders. Extensive grape on tree.	Retain
221	<i>Tilia americana</i>	Basswood	20	6.0	G		Retain
222	<i>Acer negundo</i>	Manitoba Maple	47	10.0	P-F	Main branch split and cracked off. Now large open wound.	Retain
223	<i>Acer negundo</i>	Manitoba Maple	18, 10, 10, 6	6.0	F	Grape on tree. Epicormic shoots.	Retain
225	<i>Acer negundo</i>	Manitoba Maple	20, 16, 7	4.0	F	Grape on tree.	Retain
226	<i>Acer negundo</i>	Manitoba Maple	26, 12, (6<10)	7.0	F	Grape on tree.	Retain
227	<i>Acer negundo</i>	Manitoba Maple	36, 40	14.0	F	Broken branches with decaying third stump.	Retain
228	<i>Acer negundo</i>	Manitoba Maple	41	9.0	F	Broken branches with decaying third stump.	Retain
229	<i>Acer negundo</i>	Manitoba Maple	28	6.0	F-G		Remove
230	<i>Acer saccharum</i>	Sugar Maple	52	12.0	F-G	Lean towards creek 75 degrees.	Remove
231	<i>Tilia americana</i>	Basswood	20, 16	7.0	F	Suckers; dead twigs. Growth impeded by #230.	Remove
232	<i>Acer saccharum</i>	Sugar Maple	8	14.0	G		Remove
233	<i>Acer negundo</i>	Manitoba Maple	10	31.0	F		Remove
234	<i>Fraxinus americana</i>	White Ash	40, 53	10.0	P	Emerald Ash Borer (EAB).	Remove
235	<i>Acer negundo</i>	Manitoba Maple	16	5.0	F		Remove
236	<i>Fraxinus americana</i>	White Ash	19	4.0	P	EAB.	Retain
237	<i>Acer negundo</i>	Manitoba Maple	19	5.0	F	Dead twigs.	Retain
238	<i>Acer negundo</i>	Manitoba Maple	17	5.0	F		Retain
239	<i>Juglans nigra</i>	Black Walnut	23	7.0	F	Canopy pushed down by woodland trees.	Remove
240	<i>Acer saccharum</i>	Sugar Maple	55	14.0	G		Remove
241	<i>Fraxinus americana</i>	White Ash	33	10.0	P	EAB.	Remove
242	<i>Acer saccharum</i>	Sugar Maple	13	7.0	G		Remove
243	<i>Acer saccharum</i>	Sugar Maple	13	7.0	G		Remove
244	<i>Fraxinus americana</i>	White Ash	35	10.0	P	EAB.	Remove
245	<i>Juglans nigra</i>	Black Walnut	15	6.0	F-G		Remove
246	<i>Prunus serotina</i>	Black Cherry	23	7.0	G		Remove
247	<i>Acer negundo</i>	Manitoba Maple	42	10.0	G		Retain
248	<i>Fraxinus americana</i>	White Ash	16	5.0	P	EAB.	Retain
249	<i>Fraxinus americana</i>	White Ash	17	5.0	P	EAB.	Retain
250	<i>Acer saccharum</i>	Sugar Maple	12	5.0	G		Retain
251	<i>Acer saccharum</i>	Sugar Maple	27	12.0	G		Remove
252	<i>Acer saccharum</i>	Sugar Maple	11	5.0	G		Remove
253	<i>Acer negundo</i>	Manitoba Maple	20	7.0	F-G	Suckers. Previously pruned.	Retain
254	<i>Acer negundo</i>	Manitoba Maple	26	7.0	F-G	Lean towards creek. 2 stems joined.	Retain
255	<i>Acer negundo</i>	Manitoba Maple	19, 22, 37	12.0	F	Dead branches.	Remove
256	<i>Acer platanoides</i>	Norway Maple	22	6.0	G		Retain
257	<i>Acer negundo</i>	Manitoba Maple	13	4.0	F	Broken branches.	Retain
258	<i>Acer platanoides</i>	Norway Maple	14	5.0	G		Remove
259	<i>Juglans cinerea</i>	Butternut	19	5.0	F		Retain
260	<i>Acer platanoides</i>	Norway Maple	36	7.0	G		Remove
261	<i>Acer platanoides</i>	Norway Maple	24	10.0	G		Remove
262	<i>Fraxinus americana</i>	White Ash	20	6.0	P		Remove
263	<i>Acer negundo</i>	Manitoba Maple	12	5.0	F	Suckers.	Remove
264	<i>Acer platanoides</i>	Norway Maple	15	6.0	G		Remove
265	<i>Acer negundo</i>	Manitoba Maple	26, 20	10.0	G		Retain

Tag #	Species Name		Tree Dimensions		Health Condition	Notes	Action

1 INTRODUCTION

Terraprobe Inc. (Terraprobe) was retained by Aquafor Beech Limited to conduct a geotechnical investigation for the proposed Pedestrian Bridges at Applewood Creek, on the Lakeview Golf Course located at 1190 Dixie Road in the City of Mississauga, Ontario.

This report encompasses the results of the geotechnical investigation conducted for the subject site to determine the prevailing subsurface soil and shallow ground water conditions. This information is used to provide geotechnical engineering recommendations for the design of the proposed pedestrian bridge foundations. In addition, comments are also included on pertinent construction aspects including excavation, backfill and ground water control and scour protection.

2 PROJECT AND SITE DESCRIPTIONS

Aquafor Beech Limited is conducting an Environmental Assessment (EA) for the Applewood Creek project which extends through the Lakeview golf Course, located at 1190 Dixie Road in the City of Mississauga, Ontario. It is understood that the project will include implementation of erosion control measures for the creek banks and replacement of select bridges. It is further understood that the total length of the creek through the golf course is approximately 1,300 m and five (5) pedestrian bridges will be replaced along the creek through the golf course. The general location of the subject site is presented on Figure 1.

3 INVESTIGATION PROCEDURE

The field investigation was conducted on April 27 and 28, 2020, and consisted of drilling and sampling a total of nine (9) boreholes (Boreholes 1 and 2 for new bridge near Bridge No. 8; Boreholes 3 and 4 for new bridge near Bridge No. 7; Borehole 5 for new bridge between Bridge Nos. 5 and 6; Boreholes 7 and 8 for new bridge near Bridge No. 3 and Boreholes 8 and 9 for new bridge near Bridge No. 2) to auger refusal depths of about 2.1 to 3.9 m below grade (Elev. 84.7 to 90.7 m). Generally, two boreholes (one borehole on each side of the creek) were advanced in the vicinity of each of the proposed bridge locations. However, for the bridge located between existing Bridge Nos. 5 and 6, only one borehole (Borehole 5) could be carried out at this location as the west bridge abutment will be located in what is presently a pond. As such a borehole could not be advanced at that location. The approximate location of the boreholes is shown on the enclosed Borehole Location Plan (Figure 2).

The boreholes were surveyed for coordinates and geodetic elevation with a Trimble R10 Receiver connected to the Global Navigation Satellite System. The elevations noted on the Borehole Logs are approximate, and provided only for the purpose of relating borehole soil stratigraphy, and should not be used or relied on for other purposes.

The borings were drilled by a specialist drilling contractor using a Mini Mole drill rig with power auger. The borings were advanced using continuous flight solid-stem augers, and were sampled at regular

intervals with a conventional 50 mm diameter split barrel sampler when the Standard Penetration Test (SPT) was carried out (ASTM D1586). The field work (drilling, sampling and testing) was observed and recorded by a member of our field engineering staff, who logged the borings and examined the samples as they were obtained.

All samples obtained during the field investigation were sealed in clean plastic jars, and transported to our geotechnical testing laboratory for detailed inspection and testing. Borehole samples were examined (tactile) in detail by a geotechnical engineer, and classified according to visual and index properties. Laboratory testing consisted of water content determination on all samples; and a Sieve and Hydrometer analysis on three (3) selected soil samples (Borehole 4, Sample 4, Borehole 5, Sample 3 and Borehole 7, Sample 1). The results of the geotechnical laboratory testing are plotted on the enclosed Borehole Logs at respective sampling depths. The results of laboratory tests (Sieve and Hydrometer analysis tests) are also summarized in Section 4.5 of this report, and appended.

Ground water levels were monitored in the boreholes upon completion of drilling. Standpipe type piezometer comprising 25 mm diameter PVC tubing was installed in Boreholes 4 and 8 to facilitate ground water level monitoring. The PVC tubing was saw slotted near its base and fitted with a bentonite clay seal as shown on the accompanying Borehole Logs. Water levels in the piezometers were measured on May 13, 2020 about two weeks following the installation. The results of ground water level are presented in Section 4.6 of this report.

4 SUBSURFACE CONDITIONS

The specific soil conditions encountered at each borehole location are presented in greater detail on the Borehole Logs, with a summary of the general subsurface soil conditions outlined below. This summary is intended to correlate this data to assist in the interpretation of the subsurface conditions at the site. Refer to Borehole Logs for stratigraphic and other details.

It should be noted that the subsurface conditions are confirmed at the borehole locations only, and may vary between and beyond the borehole locations. The stratigraphic boundaries between the various strata as shown on the Borehole Logs are based on non-continuous sampling. These boundaries represent an inferred transition between the various strata, rather than a precise plane of geologic change.

In summary, a surficial topsoil layer was encountered at the ground surface in all boreholes. The topsoil was underlain by a layer of earth fill materials in some boreholes. The native deposits consisted of generally loose sandy silt to silty sand or sand (in some boreholes) which was in turn underlain by clayey silt glacial till deposit which extended to the inferred bedrock. Rock coring to characterize and confirm bedrock was beyond our scope of work, and therefore was not carried out.

4.1 Topsoil

Topsoil layer (150 to 300 mm thick) was encountered at the ground surface at all Borehole locations. The topsoil thicknesses were measured from the collar of the borings and are approximate, and may vary between and beyond the boreholes. The topsoil thickness noted on the Borehole Logs refers to distinct topsoil layer present at the borehole location, however, organic inclusions extended deeper than the topsoil thickness layer noted on the Borehole Logs.

Topsoil and aggregate thickness may vary beyond the borehole location. The above data may not be sufficient for estimating topsoil or aggregate quantities and/or associated costs.

4.2 Earth Fill

A zone of earth fill consisting of sand to silty sand with terrace clay, trace rootlets and organic staining was encountered beneath the surficial topsoil layer in Boreholes 1 to 3 and 5. The earth fill materials extended to a depth of ranging from about 0.8 to 1.1 m below grade (Elev. 90.6 to 93.0 m).

The Standard Penetration Test results ('N' Values) obtained from the earth fill materials varied from 3 to 12 blows per 300 mm of penetration, indicating a loose to compact relative density (generally loose).

The measured water contents of the earth fill soil samples typically ranged from 17 to 30 percent by weight, indicating a moist to wet condition. High water contents, i.e. 30 percent is likely due to the presence of organics.

4.3 Sandy Silt to Silty Sand and Sand

Underlying the surficial topsoil in Boreholes 4, and 6 to 9 and the fill in Borehole 5, an undisturbed native cohesionless soil comprising sandy silty to silty sand and sand (hereafter referred to as the "silt and sand unit") with trace clay to clayey was encountered and extended to the a depth ranging from 0.4 to 2.3 m below grade (Elev. 87 to 91.4 m).

The Standard Penetration Test results ('N' Values) obtained from the silt and sand unit ranged from 2 to 11 blows per 300 mm of penetration, indicating a loose to compact relative density (generally loose).

The measured water contents of these soil samples ranged from 17 to 34 percent by weight, indicating a wet condition.

4.4 Clayey Silt (Glacial) Till

Clayey silt (glacial) till was encountered below the fill in Boreholes 1 to 3 and below the silt and sand unit in the remaining boreholes, and extended to the surface of the inferred bedrock, i.e. a depth ranging

from 1.2 to 3.0 m below grade (Elev. 86.3 to 91.8 m). Gravel was widely dispersed throughout the deposit and sporadic shale fragments inclusion was noted within this deposit.

The Standard Penetration Test results ('N' Value) obtained from the clayey silt soil deposit ranged from 8 to 54 blows per 300 mm of penetration, indicating a stiff to hard consistency.

The measured water contents of these soil samples ranged from 11 to 23 percent by weight, indicating a moist condition.

4.5 Inferred Bedrock

Weathered shale was inferred beneath the clayey silt glacial till deposit in all boreholes at depths ranging from about 1.2 to 3.0 m below grade, i.e. elevation ranging from 86.3 m (Borehole 8) to 91.8 m (Borehole 2). It must be noted that the presence of bedrock (Georgian Bay Formation) was inferred from the auger/sampling spoon refusal and/or presence of shale fragments in the sample(s). Auger/sampling spoon refusal may also be indicative of a presence of cobbles/boulders. Bedrock confirmation and characterization through rock coring was beyond the scope of our work and was not carried out. Therefore, it must be noted that the depth of bedrock at the borehole locations may be different from the inferred depth noted on the borehole logs. Rock coring should be undertaken if accurate confirmation of the bedrock level and its characterization are inherently important to the project design and construction, and a variation in the elevation/depth of bedrock cannot be tolerated.

The bedrock of the Georgian Bay Formation, typically found in the general area, is a deposit predominantly comprising thin to medium bedded blue-grey shale of Upper Ordovician age. The bedrock contains interbeds of grey calcareous shale, limestone/dolostone and calcareous sandstone which are discontinuous and nominally 50 to 300 mm thick.

4.6 Geotechnical Laboratory Test Results

The geotechnical laboratory testing consisted of natural water content determination for all samples, while a Sieve and Hydrometer analysis was conducted on selected soil samples. A summary of the Sieve and Hydrometer (grain size) analysis results is presented as follows:

Borehole No. Sample No.	Depth Below Grade	Percentage (by weight)				Descriptions (MIT System)
		Gravel	Sand	Silt	Clay	
Borehole 4, Sample 4	2.5 m	2	7	63	28	CLAYEY SILT, trace sand, trace gravel
Borehole 5, Sample 3	1.8 m	0	7	69	24	CLAYEY SILT, trace sand

Borehole No. Sample No.	Depth Below Grade	Percentage (by weight)				Descriptions (MIT System)
		Gravel	Sand	Silt	Clay	
Borehole 7, Sample 1	0.3 m	0	70	18	12	SAND, some silt, some clay

4.7 Ground Water

The depth of ground water and caving was measured in the boreholes immediately following the drilling. A piezometer was installed in Boreholes 4 and 8 upon completion of drilling. The stabilized ground water levels were measured in the piezometers on May 13, 2020 (about two weeks after the drilling). The ground water levels measurements are shown on the Boreholes Logs, and are summarized as follows:

Borehole No.	Depth of Borehole	Depth to Cave	Water Level at the Time of Drilling	Water Level in Piezometer on May 13, 2020	
				Depth	Elevation
1	3.1 m	open	1.5 m		No piezometer installed
2	3.1 m	open	Dry		No piezometer installed
3	2.5 m	open	1.7 m		No piezometer installed
4	3.9 m	open	1.2 m	1.1 m	92.6 m
5	3.9 m	open	1.8 m		No piezometer installed
6	2.1 m	open	Dry		No piezometer installed
7	3.1 m	open	2.7 m		No piezometer installed
8	3.1 m	open	2.7 m	2.0 m	85.8 m
9	3.1	open	Dry		No piezometer installed

Ground water levels may fluctuate with time and seasonally depending on the amount of precipitation and surface runoff. Wet soils may be encountered to about 0.6 m higher than the water levels noted above due to capillary rise in fine cohesionless silt/sand soils and will be influenced by the creek water level.

5 DISCUSSIONS AND RECOMMENDATIONS

The following discussion and recommendations are based on the factual data obtained from this investigation and are intended for the use of the owner and the design engineer. Contractors bidding or providing services on this project should review the factual data and determine their own conclusions regarding construction methods and scheduling.

This report is provided on the basis of these terms of reference and on the assumption that the design features relevant to the geotechnical analyses will be in accordance with applicable codes, standards and guidelines of practice. If there are any changes to the site development features or there is any additional information available relevant to the interpretations made of the subsurface information with respect to the geotechnical analyses or other recommendations, then Terraprobe should be retained to review the implications of these changes with respect to the contents of this report.

5.1 Foundation

As noted before, nine (9) boreholes (Boreholes 1 and 2 for new bridge near Bridge No. 8; Boreholes 3 and 4 for new bridge near Bridge No. 7; Borehole 5 for new bridge between Bridge Nos. 5 and 6; Boreholes 7 and 8 for new bridge near Bridge No. 3 and Boreholes 8 and 9 for new bridge near Bridge No. 2)) were advanced on each side of the creek, at or near the proximity of the proposed bridge abutments) to auger refusal depths of about 2.1 to 3.9 m below grade (Elev. 84.7 to 90.7 m). Beneath a surficial topsoil veneer, Boreholes 1 to 3 and 5 encountered earth fill materials extending to a depth of about 0.8 to 1.1 m below grade (Elev. 90.6 to 93 m). Underlying the surficial topsoil in Boreholes 4, and 6 to 9 and the fill in Borehole 5, an undisturbed native cohesionless soil comprising loose to compact sandy silty to silty sand and sand (the “silt and sand unit”) with trace clay to clayey was encountered and extended to the a depth ranging from 0.4 to 2.3 m below grade (Elev. 87 to 91.4 m). Clayey silt (glacial) till was encountered below the fill in Boreholes 1 to 3 and below the silt and sand unit in the remaining boreholes, and extended to the surface of the inferred bedrock, i.e. a depth ranging from 1.2 to 3.0 m below grade (Elev. 86.3 to 91.8 m). Rock coring to confirm and characterize the bedrock was beyond our scope of work, and was not conducted, therefore the actual depth(s) of the bearing stratum (bedrock) may vary from the inferred bedrock depth(s) noted on the borehole logs.

It is reiterated that for the bridge located between existing Bridge Nos. 5 and 6, only one borehole (Borehole 5) could be carried out at this location as the west bridge abutment will be located in what is presently a pond. As such a borehole could not be advanced at that location. Once the pond is drained and/or infilled, additional boreholes or test pits should be carried out to confirm the bedrock elevation in this area.

A conventional spread footing foundation approach would appear to be the most feasible based on the relatively shallow depth of inferred bedrock.

The existing earth fill materials are not suitable for the support of proposed bridge foundations, and the generally loose silt and sand unit and stiff to hard clayey silt glacial till will likely not provide a consistent bearing stratum also. As such, we recommend that all foundations be supported on the underlying bedrock.

Spread footing foundations supported on bedrock may be designed for a net geotechnical reaction of 1,000 kPa at Serviceability Limit State (SLS) and a factored geotechnical resistance of 1,500 kPa at Ultimate Limit State (ULS). The anticipated settlement for foundations supported on sound bedrock in conjunction with the above recommended geotechnical resistance (SLS) should be 19 mm or less.

The geotechnical resistances values given above are for concentric, vertical loads only. Effects of load inclination and eccentricity should be taken into account as illustrated in the *Canadian Highway Bridge Design Code (CHBDC) CAN/CSA-S6-06*, Clause 6.7.3 and Clause 6.7.4.

Resistance to lateral forces/sliding resistance between the concrete footing and the bedrock should be evaluated in accordance with the CHBDC 2014. The sliding resistance may be computed based on an ultimate coefficient of friction of 0.5 between the concrete and bedrock.

For conventional structure design the resistance derived from passive earth pressure is generally not considered as a resisting force against sliding because a structure must deflect significantly to develop the full passive resistance.

Deep foundations (augured caisson and piles) are not considered to be an economical alternative because the bridge can be supported on a less costly foundation alternative i.e. spread footings.

Although helical pile option is an economical foundation solution for these relatively light bridges. At this site, the inferred bedrock is likely to be present at relatively shallow depth and therefore helical piers will encounter refusal at relatively shallow depths, and may not be a feasible foundation option at this site.

5.2 Design Frost Depth

Strip footings including any associated concrete wing walls/retaining walls, should be founded at a minimum depth of 1.2 m below permanent soil cover to provide adequate protection against frost penetration, as per OPSD 3090.101.

5.3 Scour Protection

The base of the bridge abutments should be protected from scour. Proper erosion and scour protection must be provided along the sides of the creek at the bridge location and for an adequate distance beyond. Suitably designed rip-rap can be used to provide protection of the bridge abutments as well as any forward slopes. The size and thickness of the rip-rap stones should be determined by a geomorphologist

or other qualified professional. The rip-rap should be separated from the native soils or embankment material with a suitable geotextile filter fabric or a filter zone of granular material.

Since storm events will cause temporary high water levels at the site, these elevated water levels should be considered when determining the lateral and vertical extent of the scour protection. The scour depth is also dependent upon the hydrology of the channel, its cross-section and the engineering properties of the materials below the streambed.

5.4 Lateral Earth Pressure for Abutments and Retaining Walls

If the abutment is allowed to yield (unrestrained system) then, active horizontal earth pressure should be used for the design. If the abutment is not allowed to yield (restrained system) then, at-rest horizontal earth pressures should be used for the design.

Where the backfill to the bridge abutment is placed in accordance with OPSD 3101.150 (Abutment Backfill Minimum Granular Requirement), as recommended; the lateral earth pressure will be governed by the properties of the material within the backfill limits shown in the respective OPSD, i.e. a line projected up at 1.5H:1V for granular backfill.

Walls subject to unbalanced earth pressures must be designed to resist a pressure that can be calculated based on the following equation:

$$P = K[\gamma(h - h_w) + \gamma' h_w + q] + \gamma_w h_w$$

where,

P = the horizontal pressure at depth, **h** (m)

K = the earth pressure coefficient

h_w = the depth below the ground water level (m)

γ = the bulk unit weight of soil, (kN/m³)

γ' = the submerged unit weight of the exterior soil, ($\gamma - 9.8$ kN/m³)

q = the complete surcharge loading (kPa)

Where the wall backfill can be drained effectively to eliminate hydrostatic pressures on the wall that would otherwise act in conjunction with the earth pressure, this equation can be simplified to:

$$P = K[\gamma h + q]$$

The factored geotechnical resistance to sliding of foundation elements is developed by friction between the base of the footing and the soil. This friction (**R**) depends on the normal load of the soil contact (**N**) and the frictional resistance of the soil (**tan φ**) expressed as **R_f = N tanφ**, which is the unfactored resistance. The factored geotechnical resistance at ULS is **R_f = 0.8 N tanφ**.

Backfill to the abutment walls should be in accordance with OPSS 902. Granular backfill should be placed to the extents shown in OPSD 3101.150. The backfill should consist of free-draining, non-frost susceptible granular materials in accordance with OPSS MUNI 1010. The design of the abutment should incorporate a subdrain as shown in OPSD 3101.150. The function of this drain and backfill is to preclude hydrostatic and frost forces from acting on the abutment. All granular fill (meeting OPSS MUNI 1010 Specifications) should be placed in loose lifts not exceeding 150 mm thick and should be compacted to at least 95 percent Standard Proctor Maximum Dry Density (SPMDD), in accordance with OPSS MUNI 501.

Earth pressures acting on the structure should be computed in accordance with Clause 6.12 of the CHBDC S6-14 and according to Clause 6.12.3 of the CHBDC S6-14; a compaction surcharge should also be added. For soils with an angle of internal friction ranging from 30° to 35° the magnitude should be 12 kPa at the top of the fill decreasing linearly to 0 kPa at a depth of 1.7 m; or decreasing linearly to 0 kPa at a depth of 2.0 m for soils with an angle of internal friction that exceeds 35° .

Earth pressure coefficients are dependent on the material used as backfill and typical values are provided in the following table.

Wall Condition	Earth Pressure Coefficient (K)			
	OPSS Granular A or OPSS Granular B Type II $\phi = 35^\circ$; $\gamma = 22.8 \text{ kN/m}^3$		OPSS Granular B Type I $\phi = 32^\circ$; $\gamma = 21.2 \text{ kN/m}^3$	
	Horizontal Surface Behind Wall	Sloping Surface Behind Wall (2H:1V)	Horizontal Surface Behind Wall	Sloping Surface Behind Wall (2H:1V)
Active (Unrestrained Wall)	0.27	0.38*	0.31	0.46*
At rest (restrained Wall)	0.43	-	0.47	-
Passive (Movement towards Soil Mass)	3.70	-	3.25	-

*For Wing Walls

The earth pressure coefficients in the table above are “ultimate” values that require certain structural movements for the respective conditions to be mobilized. The values to use for design can be estimated from Figure C6.6 in the Commentary to the CHBDC, S6.1-14.

5.5 Earthquake Design Parameters

According to Clause 4.5.2 of the CHBDC S6-14, Seismic analysis of a single-span bridge shall not be required, regardless of seismic zone. Otherwise this location would be considered to be Site Class B or C.

5.6 Excavation and Ground Water Control

The borehole data indicate that earth fill materials, native soils (“silt and sand unit” and clayey silt glacial till) and shale would be encountered in the excavations. Excavations must be carried out in accordance with the Occupational Health and Safety Act and Regulations for Construction Projects. These regulations designate four broad classifications of soils to stipulate appropriate measures for excavation safety.

The earth fill materials as well as native soil deposit encountered in the boreholes are classified as Type 3 Soil above and Type 4 Soil below the prevailing ground water level.

Where workmen must enter excavations advanced deeper than 1.2 m, the trench walls should be suitably sloped and/or braced in accordance with the Occupational Health and Safety Act and Regulations for Construction Projects. The regulation stipulates steepest slopes of excavation by soil type as follows:

Soil Type	Base of Slope	Steepest Slope Inclination
1	within 1.2 metres of bottom of trench	1 horizontal to 1 vertical
2	within 1.2 metres of bottom of trench	1 horizontal to 1 vertical
3	from bottom of trench	1 horizontal to 1 vertical
4	from bottom of trench	3 horizontal to 1 vertical

Minimum support system requirements for steeper excavations are stipulated in the Occupational Health and Safety Act and Regulations for Construction Projects, and include provisions for timbering, shoring and moveable trench boxes.

Excavations made in bedrock can be near vertical, provided the rock faces are scaled and maintained to preclude the possibility of spalls. Where this is not possible, protective mesh can be draped over the rock face when work is required in the area immediately beside the cut rock face.

As noted before, subsurface soil deposit may contain larger particles (cobbles and boulders) that are not specifically identified in the borehole logs. The size and distribution of such obstructions cannot be predicted with borings, because the borehole sampler size is insufficient to secure representative samples of the particles of this size. Provision should be made in excavation contracts to allocate risks associated with the time spent and equipment utilized to remove or penetrate such obstructions when encountered.

Weathered shale can be removed by a hydraulic excavator using a bucket with cutting teeth. The “harder” limestone/dolostone layers may require removal using hoe operated jackhammers. The presence of these harder layers must be referenced in the contract documents to allocate risk associated with time spent and equipment utilized to remove such obstructions.

All boreholes remained open and the measured ground water level in Boreholes 1, 3, 4, 5, 7 and 8 were noted to be at a depth of about 1.2 to 2.7 m below existing grade upon completion of drilling. Boreholes 2, 6 and 8 remained dry upon completion of drilling. The ground water levels measured in the piezometers were 1.1 m (Elev. 92.6 m at Borehole 4) and 2.0 m (Elev. 85.8 m at Borehole 8) below grade on May 13, 2020.

Based on the borehole information, ground water seepage is expected into the excavation. The amount seepage will depend upon the depth of excavation and creek water level. The ground water seepage will likely emanate from the ground water generally perched within the fill materials and from very moist to wet cohesionless silt and sand unit as well as water flow from the creek. It should be noted that the excavations carried through and below the water bearing cohesionless soils (silt and sand unit), will experience loosening and sloughing of the base and sides thus requiring wider excavation slopes.

For excavations extending into the very moist to wet silt and sand unit and/or below the prevailing ground/creek water level, it will be necessary to lower the ground water level and maintain it below the excavation base (at least 1.0 m) prior to and during the subsurface construction, and therefore positive ground water control will be required. Consideration should be given to install a skim coat of lean concrete (mud-slab) to preserve the subgrade integrity, and to provide a working platform.

In addition to the groundwater control, positive management/control/diversion of the surface and creek water will be critical for the proposed bridge construction. The design of ground and surface water control plan will depend upon site specific parameters including soil permeability, subsurface stratigraphy, height of lift, size of work area and prevalent ground water table. The design of a suitable dewatering, groundwater and surface water control system is the contractor's responsibility. Dewatering of more than 50,000 litres/day would require a permit from the Ministry of Environment.

5.7 Approach Embankments

Settlement of the underlying soils in the footprint area of the approach embankments will be negligible provided that the bridge approach embankments do not exceed a height of about 2 m.

All organic and unsuitable soils must be removed from the footprint area of the approach embankments. The embankment fill should be placed on approved and properly prepared subgrade in shallow lifts not exceeding 150 mm in thickness and compacted in accordance with OPSS MUNI 501. Fill materials used for constructing the approaches should consist of approved acceptable indigenous earth fill, select subgrade material or non-cohesive earth fill. Embankments constructed with these fill materials should be designed with a side slope inclination of 2 Horizontal to 1 Vertical (2H:1V) or flatter.

Proper erosion control measures should be implemented both during construction and permanently. Temporary erosion and sediment control must be provided in accordance with OPSS 805 (Temporary

Erosion and Sediment Control). Fill slopes should be provided with permanent erosion protection in accordance with OPSS 803 (Sodding) and/or OPSS MUNI 804 (Seed and Cover).

6 LIMITATIONS AND RISK

6.1 Procedures

This investigation has been carried out using investigation techniques and engineering analysis methods consistent with those ordinarily exercised by Terraprobe and other engineering practitioners, working under similar conditions and subject to the time, financial and physical constraints applicable to this project. The discussions and recommendations that have been presented are based on the factual data obtained by Terraprobe.

It must be recognized that there are special risks whenever engineering or related disciplines are applied to identify subsurface conditions. Even a comprehensive sampling and testing programme implemented in accordance with the most stringent level of care may fail to detect certain conditions. Terraprobe has assumed for the purposes of providing design parameters and advice, that the conditions that exist between sampling points are similar to those found at the sample locations. The conditions that Terraprobe has interpreted to exist between sampling points can differ from those that actually exist.

It may not be possible to drill a sufficient number of boreholes or sample and report them in a way that would provide all the subsurface information that could affect construction costs, techniques, equipment and scheduling. Contractors bidding on or undertaking work on the project should be directed to draw their own conclusions as to how the subsurface conditions may affect them, based on their own investigations and their own interpretations of the factual investigation results, cognizant of the risks implicit in the subsurface investigation activities so that they may draw their own conclusions as to how the subsurface conditions may affect them.

6.2 Changes in Site and Scope

It must also be recognized that the passage of time, natural occurrences, and direct or indirect human intervention at or near the site have the potential to alter subsurface conditions. Groundwater levels are particularly susceptible to seasonal fluctuations.

The discussion and recommendations are based on the factual data obtained from this investigation made at the site by Terraprobe and are intended for use by the owner and its retained designers in the design phase of the project. If there are changes to the project scope and development features, the interpretations made of the subsurface information, the geotechnical design parameters and comments relating to constructability issues and quality control may not be relevant or complete for the revised project. Terraprobe should be retained to review the implications of such changes with respect to the contents of this report.

This report was prepared for the express use of Aquafor Beech Limited and their retained design consultants and is not for use by others. This report is copyright of Terraprobe Inc. and no part of this report may be reproduced by any means, in any form, without the prior written permission of Terraprobe Inc. and Aquafor Beech Limited who are the authorized users.

It is recognized that the regulatory agencies in their capacities as the planning and building authorities under Provincial statutes, will make use of and rely upon this report, cognizant of the limitations thereof, both expressed and implied.

We trust the foregoing information is sufficient for your present requirements. If you have any questions, or if we can be of further assistance, please do not hesitate to contact us.

Yours truly,

Terraprobe Inc.

Osbert (Ozzie) Benjamin, P. Eng.
Senior Project Manager, Geotechnical Department

M. Tanos, P. Eng.
Consulting Principal
